Abstract

In this thesis, we propose a Binary Global-Best Harmony Search (BGBHS) Algorithm to solve different instances of the Set Covering Problem (SCP). The SCP is considered a classic combinatorial optimization problem, belonging to the class \mathcal{NP} -hard problem and have many practical applications. In this document we consider applying BGBHS and Modified BGBHS supported in adaptive adjustment of probability parameter p in the Bernoulli trials when the harmonies are created. The different results presented in this thesis show that our algorithm is a good alternative at a low cost to solve the SCP.

Keywords: Binary Global-Best Harmony Search, Metaheuristic, Set Covering Problem.

1 Introduction

Every process has a potential to be optimized. the vast majority of companies is involved in solving optimization problems every day. Indeed, many challenging applications in science and industry can be formulated as optimization problems.

Metaheuristics are a branch of optimization in computer science and applied mathematics that are related to algorithms and computational complexity theory. metaheuristics are raising a large interest in diverse technologies, industries, and services since they proved to be efficient algorithms in solving a wide range of complex real-life optimization problems in different domains.

The instantiation of an metaheuristic requires to choose among a set of different possible components and to assign specific values to all free parameters. The author refer to such an instantiation as a configuration, which corresponds to a crucial point in the resolution of the SCP [1].

The SCP is a well-known mathematical problem, which tries to cover a set of needs at the lowest possible cost. SCP is very important in practice, as it has been used to model a large range of problems like scheduling, manufacturing, service planning, information retrieval, among others.

In an attempt to resolve the SCP, a variation of Harmony Search metaheuristic in binary domain was designed. The main goal is to find a global optimal solution, experimentation using SCP instances from the OR-library [2]. The experiments shows that the developed algorithm generates good solutions for each instance.

1.1 Main goal

Solving the SCP using the Binary Global-Best HS metaheuristic algorithm.

1.2 Specific objectives

- Solve the SCP with the BGBHS metaheuristic and compare the results with benchmark of Beasley
- Introduce new operators that make the results more close to the global optimum.
- Search nearest optimal solutions to problems in the SCP.
- Compare and analyze the results using different resolution strategies.

2 Conceptual Framework

Optimization problems are encountered in many domains: BigData, engineering, logistics, and business. An optimization problem may be defined by the couple (S, f) , where S represents the set of feasible solutions, and $f : S \Rightarrow \mathbb{R}$ the objective function to optimize. The objective function assigns to every solution $s \in S$ of the search space a real number indicating its worth. The objective function f allows to define a total order relation between any pair of solutions in the search space.

The global optimum is defined as a solution $s^* \in S$ and it has a better objective function than all solutions of the search space, that is, $\forall s \in S, f(s^*) \leq f(s)$.

2.1 Metaheuristics

Definition The *meta* and *heuristic* are Greek words, *meta* it means *higherlevel* and *heuristics* means *to find, to know or to discover*. Metaheuristics are a set of intelligent strategies to enhance the efficiency of heuristic procedures.

A metaheuristic will be successful on a given optimization problem if it can provide a balance between exploration and exploitation. Exploration means to generate diverse solutions so as to explore the search space on the global scale, while exploitation means search in a local region by exploiting the information that a current good solution is found in this region. exploration, often by use of randomization, which enables an algorithm to have the ability to jump out of any local optimum so as to explore the search globally.

Classification The different metaheuristic approaches can be characterized by different aspects concerning the search path they follow or how memory is exploited [3]. A majority of these algorithms has a stochastic behavior and mimics biological or physical processes.

The classification presented was proposed by Beheshti et al. [4], and can be understood better as shown in the (Figure 1).

Trajectory methods vs. discontinuous methods The different between this metaheuristics is whether they follow one single search trajectory corresponding to a closed walk on the neighborhood graph or whether larger jumps in the neighborhood graph are allowed. Examples of this classification are: tabu search and simulated annealing. These methods usually allow moves to worse solutions to be able to escape from local minima.

The generation of starting solutions corresponds to jumps in the search space; these algorithms, in general, follow a discontinuous walk with respect to the neighborhood graph used in the local search.

Population-based vs. single-point search

Memory usage vs. memoryless methods

One vs. various neighborhood structures

Dynamic vs. static objective function

2.2 Nature-inspired vs. non-nature inspiration

Operator Unitary procedure for transforming information or implement the behavior of the algorithm.

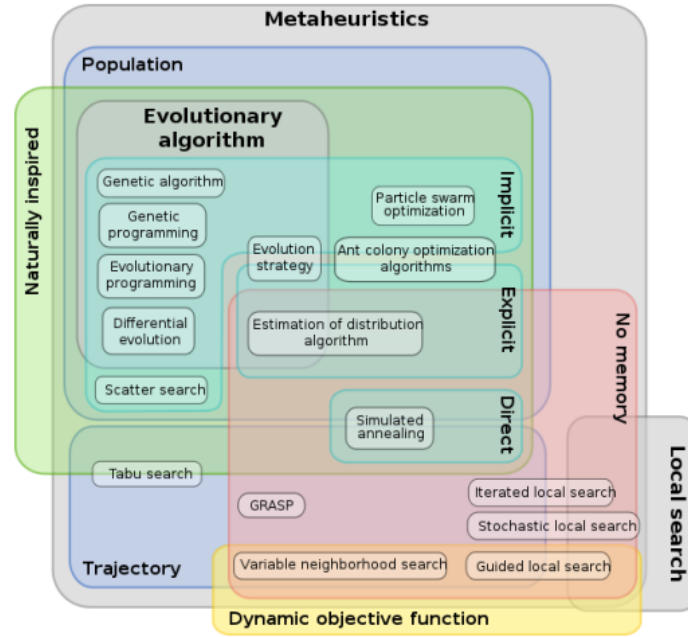

Fig. 1. Classification of Metaheuristic

Solution Array of n columns containing a solution for a given problem. In the binary case, the possible values are 0 and 1.

Constrain Conditions to be met to find a viable solution.

Benchmark Optimal set of known problem instances to validate the propose algorithm.

Objective Function Implements the mathematical expression representing the problem to solve. The guiding objective function is related to the goal to achieve.

Fitness Value resulting by applying the objective function to solution.

Matrix of Costs Consist of n columns vector containing the cost associated with each problem variable.

Optimal Value Solution with the best fitness.

Domain Set of possible values for the variable.

Matrix A Matrix containing the restrictions for the given problem.

RPD Relative Percentage Deviation.

Harmony Memory Memory space which includes the population of the solution vectors.

Harmony Memory Size Defines the amount of harmonies that can be stored in HM.

Harmony Memory Consideration Rate (HMCR) In memory consideration, the value of decision variable x'_1 is randomly selected from the historical values, other decision variables, $(x'_2, x'_3, \dots, x'_N)$ are sequentially selected in the same manner with probability where $\text{HMCR} \in (0,1)$.

Pitch Adjusting Rate (PAR) Each decision variable x'_i assigned a value by memory considerations is pitch adjusted with the probability of PAR where $\text{PAR} \in (0,1)$.

3 Theoretical Framework

3.1

3.2 Set Covering Problem

SCP formulation The SCP is a well-known mathematical problem, which tries to cover a set of needs at the lowest possible cost. The SCP was included in the list of 21 \mathcal{NP} -*complet* problems of Karp [5]. There are many practical uses for this problem, such as: crew scheduling [6, 7], location of emergency facilities [8, 9], production planning in industry [10, 11, 12], vehicle routing [13, 14], ship scheduling [15, 16], network attack or defense [17], assembly line balancing [18, 19], traffic assignment in satellite communication systems [20, 21], simplifying boolean expressions [22], the calculation of bounds in integer programs [23], information retrieval [24], political districting [25], crew scheduling problems in airlines [26], among others. The SCP can be formulated as follows:

$$\text{Minimize } Z = \sum_{j=1}^n c_j x_j \quad (1)$$

Subject to:

$$\sum_{j=1}^n a_{ij} x_j \geq 1 \quad \forall i \in I \quad (2)$$

$$x_j \in \{0, 1\} \quad \forall j \in J \quad (3)$$

Let $A = (a_{ij})$ be a $m \times n$ 0-1 matrix with $I = \{1, \dots, m\}$ and $J = \{1, \dots, n\}$ be the row and column sets respectively. We say that column j can be cover a row i if $a_{ij} = 1$. Where c_j is a nonnegative value that represents the cost of selecting the column j and x_j is a decision variable, it can be 1 if column j is selected or 0 otherwise. The objective is to find a minimum cost subset $S \subseteq J$, such that each row $i \in I$ is covered by at least one column $j \in S$.

In the following section, we present a simple way to understand the SCP, through an example:

SCP sample solution Imagine that an ambulance station can meet the needs of an geographic zone. Similarly the ambulance station can cover all the needs of the nearby areas. For example, if a station is built in Zone 1 (Figure 3) ambulance station can meet the needs of neighboring areas, that is, it could also cover: Zone 1, Zone 2, Zone 3 and Zone 4. This can be appreciated in equation (5).

In this example, we must fulfill the need to cover the geographical areas defined in accordance with the restrictions. The restriction of this case is that all areas must be covered by at least one ambulance station and the goal is to minimize the number of stations built, the cost of building a station is the same for all areas. The x_j variable represents the area j which is 1 if the ambulance station is built, and will be 0 if not. As above, it can be formulated as follows:

$$\text{Min } c_1 x_1 + c_2 x_2 + c_3 x_3 + c_4 x_4 + c_5 x_5 + c_6 x_6 + c_7 x_7 + c_8 x_8 + c_9 x_9 + c_{10} x_{10} + c_{11} x_{11} \quad (4)$$

Subject to:

$$x_1 + x_2 + x_3 + x_4 \geq 1 \quad (5)$$

$$x_1 + x_2 + x_3 + x_5 \geq 1 \quad (6)$$

$$x_1 + x_2 + x_3 + x_4 + x_5 + x_6 \geq 1 \quad (7)$$

$$x_1 + x_3 + x_4 + x_6 + x_7 \geq 1 \quad (8)$$

$$x_2 + x_3 + x_5 + x_6 + x_8 + x_9 \geq 1 \quad (9)$$

$$x_3 + x_4 + x_5 + x_6 + x_7 + x_8 \geq 1 \quad (10)$$

$$x_4 + x_6 + x_7 + x_8 \geq 1 \quad (11)$$

$$x_5 + x_6 + x_7 + x_8 + x_9 + x_{10} \geq 1 \quad (12)$$

$$x_5 + x_8 + x_9 + x_{10} + x_{11} \geq 1 \quad (13)$$

$$x_8 + x_9 + x_{10} + x_{11} \geq 1 \quad (14)$$

$$x_9 + x_{10} + x_{11} \geq 1 \quad (15)$$

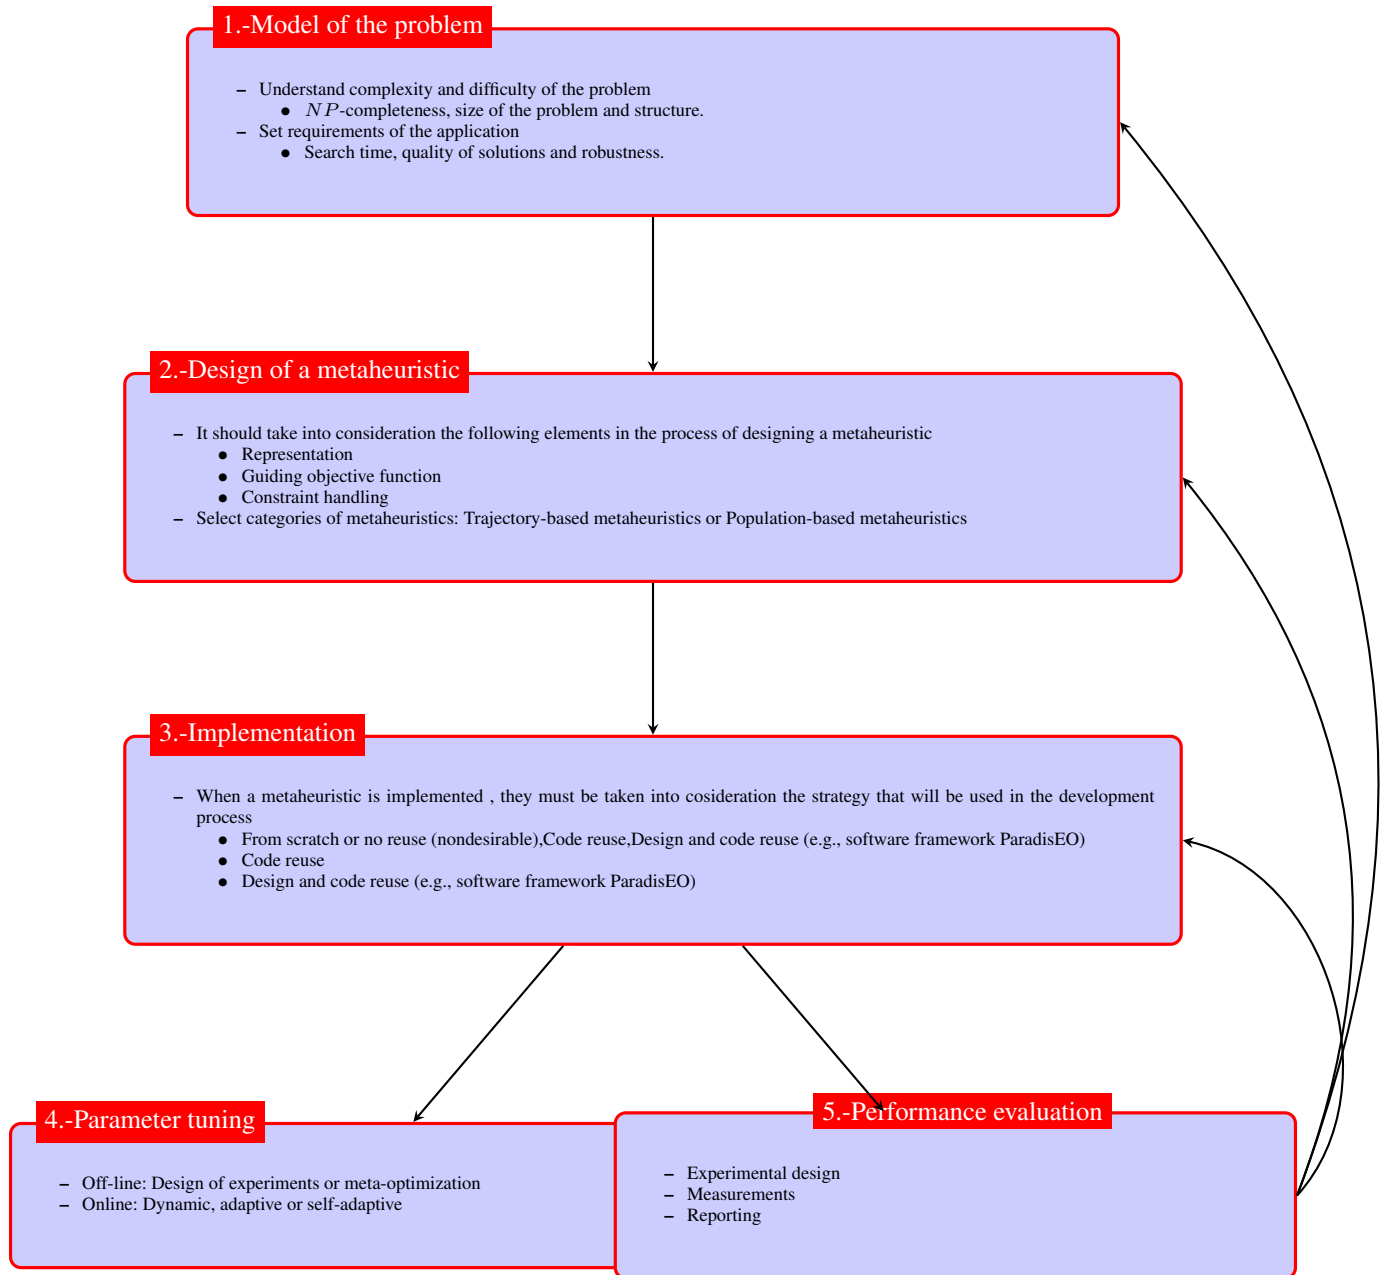

Fig. 2. Guidelines for solving SCP.

Fig. 3. Set Covering Problem example.

The first constraint (5) indicates that to cover zone 1, it is possible to locate a station in the same area or in the border. The following restriction is for zone 2 and so on. One possible optimal solution for this problem is to locate ambulance stations in zones 3, 8 and 9. That is, $x_3 = x_8 = x_9 = 1$ y $x_1 = x_2 = x_4 = x_5 = x_6 = x_7 = x_{10} = x_{11} = 0$. As shown in (Figure 4).

We propose solve the SCP, with a variation metaheuristic Harmony Search (HS) called Binary Global-Best Harmony Search to obtain satisfactory solutions within a reasonable time. HS mimics the process of musical improvisation, where musicians make adjustments in tone to achieve aesthetic harmony.

Harmony Search Metaheuristic Harmony Search (HS) is a population-based metaheuristic algorithm inspired from the musical process of searching for a perfect state of Harmony or Aesthetic Quality of a Harmony (AQH). The HS was proposed by Z. W. Geem et al. [27].

In other words, the main idea of the HS metaheuristic is to mimic the process performed by musicians when they try to play a beautiful harmony.

For the purpose of properly understand what is looking like a good solution in this metaheuristic, we must know the meaning of AQH, this concept and others are defined below.

The AQH in an instrument it is essentially determined by its pitch (or frequency), sound quality, and amplitude (or loudness). The sound quality is mainly determined by the harmonic content that is in turn determined by the waveforms or modulations of the sound signal. However, the harmonics that it can generate will largely depend on the pitch or frequency range of the particular instrument [28].

Different notes have different frequencies. For example, the note A has a fundamental frequency of $f_0 = 440Hz$. The fundamental frequency of each note can be seen in (Table 1).

Given the above, it is established that a good harmony has good AQH.

The pitch of each musical instrument determines the AQH, just as the fitness function values determines the quality of the decision variables.

In the music improvisation process, all musicians sound pitches within possible range together to make one harmony.

Fig. 4. Set Covering Problem solution.

If all pitches make a good harmony, each musician stores in his memory that experience and possibility of making a good harmony in increased next time. The same thing in optimization, the initial solution is generated randomly from decision variables within the possible range.

If the objective function values of these decision variables is good to make promising solution, then the possibility to make a good solution is increased next time.

Musical Note	Frequency
C	261,625565 Hz
D	293,664768 Hz
E	329,627557 Hz
F	349,228231 Hz
G	391,995436 Hz
A	440,000000 Hz
B	493,883301 Hz

Tabla 1: HS - Musical Notes

In this document, we focus on studying the classical SCP problem (equation 1), where we want minimize the cost.

HS operation in depth In general, the procedure for HS metaheuristic, consists of the following four steps.

Step 1: Initialization parameters

The parameters required to solve the optimization problem are specified in this step, an initial HM is filled with a population of Harmony Memory Size (HMS), harmonies are generated randomly.

In addition, the parameters of HS, that is, Harmony Memory Consideration Rate (HMCR) which determines the rate of selecting the value from the memory and Pitch Adjusting Rate (PAR) determines the probability of local improvement and number of improvisations (NI) are given when the metaheuristic begins.

Step 2: New Harmony

Improvise a new harmony from the current HM.

Step 3: Replace worst Harmony in HM

If the new generated harmony is better than the worst one in HM, then replace the worst harmony with the new one; otherwise, go to the next step.

Step 4: Check the stop criteria

If a stopping criterion is not satisfied, go to Step 2.

	<p>Each musician represents a decision variable, according to the example shown, there would be 11 musicians, since there are 11 decision variables $x_1 \dots x_{11}$.</p>
---	--

Tabla 2: HS components - Musician

	<p>The pitch range of the instrument represents the range of values that can take a decision variable. Given the nature of the problem, the possible values are $\{0, 1\}$</p>
---	---

Tabla 3: HS components - Pitch range

	<p>Musical harmony at a certain time, corresponds to a solution at a certain iteration.</p>
---	---

Tabla 4: HS components - Solution

Global-Best Harmony Search Metaheuristic To further improve the convergence performance of HS and overcome some shortcomings of HS, a new variant of HS, called Global-Best Harmony Search (GHS), was proposed by Omran and Mahdavi [29]. First, the GHS dynamically updates parameter PAR according to equation (16):

$$PAR(t) = PAR_{min} + \frac{PAR_{max} - PAR_{min}}{NI}t \quad (16)$$

where $PAR(t)$ represents the pitch adjusting rate at generation t , PAR_{min} and PAR_{max} are the minimum and maximum adjusting rate, respectively. The parameter t is the iterative variable, and parameter NI is the number of improvisations.

	Aesthetics audience, judges whether harmony is good or not. In the problem it refers to the objective function.
---	---

Tabla 5: HS components - Aesthetics audience

Binary Global-Best Harmony Search Metaheuristic The HS is good at identifying the high performance regions of the solution space in a reasonable time, but poor at performing local search [30]. Namely, there is imbalance between the exploration and the exploitation of HS. Furthermore, HS designed for continuous space cannot be directly used to solve discrete combinatorial optimization problems.

In order to overcome the drawbacks of HS, a novel binary global-best harmony search (BGHS) is designed for binary optimization problems.

Owing to better performance of GHS, some modifications to GHS are introduced to further enhance the convergence performance of GHS. Then a novel binary coded GHS, a two-phase repair operator, and a greedy selection mechanism are integrated into the BGHS. And they are described in detail as follows.
